PROCESSING-SURFACE PREPARATION - DON #17 ANODIZE PROCESS -

BONDING HK-31 MACINGIUM-THORIUM ALLOY - PROCESS VARIABLES -

INVESTIGATION OF

PURPOSE

A proposed elevon wedge design requires the use of bonded magnesium-thorium alloy. Previous experience has shown this alloy to be difficult to bond and to be subject to severe corrosion.

The Dow #17 treatment applied to HK-31 magnesium-thorium alloy* protects the surface of the alloy against corrosion and at the same time offers a potentially good surface for adhesive bonding. Therefore, the purpose of this test request was to obtain information applicable to the adhesive bonding of Dow #17 treated HK-31 magnesium-thorium alloy.

SUMMARY

Lap shear failure in the Dow #17 treated specimens with end point voltage above 70 volts was the result of failure in the Dow #17 coating itself at room temperature and below (see Tables II through VIII). The coating seemed to peel apart in layers. At test temperatures above room temperature, the lap shear failure was the result of either failure in the adhesive or failure between the adhesive and the Dow #17 coating (see Tables V through VIII).

Aging specimens at room temperature prior to priming and bonding slightly improved the bond strengths of specimens given the "standard" (70-75 volts end-point) Dow #17 treatment (see Table V and Figure 1), while aging at elevated temperatures produced a definite improvement (see Table VI).

Specimens which were given standard Dow #17 treatment, primed and then aged prior to bonding, showed no significant change in bond strengths (see Table VII and Figure 2).

Spot cleaning with M.E.K. (methyl ethyl ketone) prior to priming and bonding had no effect on the bond strengths of "standard" treated Dow #17 specimens (see Table VIII), nor did spot cleaning with M.E.K. followed by vapor degrease (see Table VIII).

* Nominal composition limits of HK31:

2.5 to 4.0% Thorium

0.45 to 1.0 % Zirconium

0.15% Max. Manganese

REPORT NO.	FGT-2000	
MODEL	B-58	
DATE	3 September	19

Specimens given the "standard" Dow #17 treatment and bonded without the application of primer produced lower bond strengths in all instances than was the case when the primer was applied (see Tables II through VII).

When magnesium-thorium specimens were given the "light" Dow #17 treatment (50-55, 60-65 volts end-point) subsequent bond strengths were superior at all test temperatures to those produced by either the "standard" or the "heavy" treatment (see Table IX). When this treatment was employed lap shear failure was the result of either failure in the adhesive or failure between the adhesive and Dow #17 coating. No failure in the coating itself was experienced. (see Table IX).

Bond strengths of specimens given the "light" Dow #17 treatment were not affected by fluid exposure test per Para. 4.2.4, MIL-A-8431 (see Table XII). The surface of the alloy itself was only slightly corroded after 30-day exposure to salt spray (see Table XII). *

Analysis by X-ray Diffraction showed the composition of the "heavy" Dow #17 coating to be entirely chromium sesquioxide (Cr₂O₃) while the composition of the "light" and "standard" coat is a mixture of hydrated and anhydrous oxides of chromium, none of these being chromium sesquioxide (see Table XVI). Thus it was shown that the composition of the Dow #17 changes as increased voltage is applied.

From the data obtained, it is concluded that a satisfactory surface for bonding with AF-31 is produced when HK-31 magnesium-thorium alloy is given the "light" (60-65 volts end-point) Dow #17 treatment and primed with EC-1459 prior to bonding. Higher end point voltages do not produce a satisfactory bonding surface whether or not the primer is applied.

PROCESSING - SURFACE PREPARATION - DOW #17 ANODIZE PROCESS -

BONDING HK-31 MAGNESIUM-THORIUM ALLOY - PROCESS VARIABLES -

INVESTIGATION OF

OBJECT

To evaluate the Dow #17 Anodize process as a bonding surface preparation for HK-31 magnesium-thorium alloy using the AF-31 adhesive system.

MATERIALS

SOURCE

AF-31 dry film adhesive

Minnesota Mining & Mfg. Co. St. Paul. Minn.

EC-1459 primer

0.063 HK-31 magnesium-thorium alloy

Dow Chemical Co., Midland, Mich.

PROCEDURE

- I. Preparation of Specimens General
 - A. Remove all dyes and other foreign materials by wiping with methyl ethyl ketone.
 - B. Vapor degrease in stabilized trichlorethylene for 10 minutes.
 - C. Apply Dow #17 treatment The Dow #17 Anodize Process consists of electrolytic treatment in an aqueous-acidic-electrolyte containing a combination of phosphate, fluoride and chromate ions. The "standard" Dow #17 treatment is applied as follows:*
 - 1. Immerse in 17% chromic acid for 5 minutes at 190°F.

Rinse in cold running water.

3. Immerse in the following solution at 160° - 180° F:

40 oz. ammonium acid fluoride

133 oz. sodium dichromate

11.5 oz. phosphoric acid (85%).

water to make 1 gallon -

- 4. Apply a direct current of 10 amps/sq.ft. to an end point voltage of 70-75 volts. In this process the part being treated acts as the anode while the treatment tank is the cathode.
- 5. Spray rinse and dry. *Application performed by The Anadite Co., Hurst, Texas.

REPORT NO. FGT-2000

MODEL B-58
DATE 3 September 1958

II. Priming and Bonding

A. Priming

- 1. Apply one brush coat of EC-1459 primer to the surfaces to be bonded.
- 2. Allow the primer to air dry two hours at room temperature.

B. Bonding

- 1. Apply one thickness of dry film adhesive (AF-31) to the primed surface of one skin.
- 2. Assemble with a second primed skin to form a 0.5 inch overlap.
- 3. Assemble on a suitable bonding pad.
- 4. Place a 1/16" thickness of curable rubber over the area to be bonded.
- 5. Place the assembly in a bonding press at room temperature and apply a uniformly distributed pressure of 150 psi over the contact area. Raise the temperature to 350 + 10°F in 35 + 5 minutes and maintain at 350°F for one hour.

III. Testing - Lap Shear

- A. Cut the bonded panel into 1" wide individual lap shear specimens forming a 0.5" x 1.0" bond area.
- B. Test in tensile shear per MIL-A-8431 under one or more of the following test temperature conditions.
 - 1. -67° F after 10 minutes at -67° F.
 - 2. Room temperature.
 - 3. 260°F after 10 minutes at 260°F.
 - 4. 450°F after 30 minutes at 450°F.
- IV. Determination of the effects of variations in processing and alterations in prebonding environmental conditions on the lap shear strengths of "standard" Dow #17 treated magnesium-thorium panels.
 - A. Determination of the effect of the omission of primer on the lap shear strengths of "standard" Dow #17 treated magnesium-thorium panels.

IV. Continued

- 1. Treat as outlined in
- 2. Bond as outlined in II except that "A" is omitted.
- 3. Mest according to III at 450°F after 30 minutes at 450°F.
- B. Determination of the effect of room temperature aging prior to bonding of "standard" Dow #17 treatment on the lap shear strengths of specimens which have not been primed.
 - 1. Dow #17 treat as outlined in I.
 - 2. Age Dow #17 treated panels at room temperature for 6, 48 and 96 hours.
 - 3. Bond according to II except that "A" is omitted.
 - 4. Test according to III at -67°F, room temperature and 260°F.
- C. Determination of the effect of room temperature aging prior to priming and bonding on the lap shear strengths of "standard" Dow #17 treated specimens.
 - 1. Dow #17 treat according to I.
 - 2. Age Dow #17 treated panels at room temperature for 6, 48 and 96 hours.
 - 3. Prime and bond according to II.
 - 4. Test according to III at -670F, room temperature, and 2600F.
- D. Determination of the effect of elevated temperature aging (500°F for 10 hours) prior to bonding of "standard" Dow #17 treatment on lap shear strengths of specimens which have not been primed.
 - 1. Treat as outlined in I.
 - 2. Age Dow #17 treated panels at 500°F for 10 hours.
 - 3. Bond according to II except that "A" is omitted.
 - 4. Test according to III at room temperature and at 260°F after 30 minutes at 260°F.
- E. Determination of the effect of elevated temperature aging (500°F for 10 hours) prior to priming and bonding on the lap shear strength of "standard" Dow #17 treated panels.
 - 1. Dow #17 treat according to I.
 - 2. Age Dow #17 treated panels at 500°F for 10 hours.
 - 3. Prime and bond according to II.
 - 4. Test according to III at room temperature and 260°F.

- V. Special Testing On Light Dow #17 (60-65 volts) Treated Magnesium-Thorium Panels
 - A. Determination of the effect of elevated temperature aging on the lap shear strength of "light" Dow #17 (60-65 volts end-point) treated AF-31 bonded magnesium-thorium panels (primer omitted).
 - 1. Treat according to I except that 60-65 volts is used as the end point voltage in C-3.
 - 2. Bond according to II except that A is omitted.
 - 3. Test according to III except that the specimens were aged at the test temperature for 100 hours. Test at 260°F and 350°F.
 - B. Determination of the effect of elevated temperature aging on the lap shear strength of "light" Dow #17 (60-65 volts end-point) treated, AF-31 bonded magnesium-thorium panels (specimens primed prior to bonding).
 - 1. Dow #17 treat according to I except that 60-65 volts is used as the end-point voltage in C-3.
 - 2. Prime and bond according to II.
 - 3. Test according to III except age at test temperature is for 100 hours. Test at 260°F and 350°F.
 - C. Determination of the effect of exposure to various fluids on the lap shear strengths of "light" Dow #17 treated (60-65 volts end-point) magnesium-thorium panels which were primed prior to bonding.
 - 1. Dow #17 treat according to I except that 60-65 volts is used as the end-point voltage in C-3.
 - 2. Prime and bond according to II.
 - 3. Test per Para. 4.2.4 MIL-A-8431.
 - D. Determination of the effect of exposure to tap water on the lap shear strength of "light" Dow #17 treated (60-65 volts end-point) magnesium-thorium panels which were not primed prior to bonding.
 - 1. Dow #17 treat according to I except that the end-point voltage in C-3 is 60-65 volts.
 - 2. Bond according to II except that A is omitted.
 - 3. Test per Para. 4.2.4 MIL-A-8431 in tap water only.

- E. Determination of the normal temperature fatigue strength of bonded "light" Dow #17 treated (60-65 volts end-point) magnesium-thorium lap shear specimens.
 - 1. Dow #17 treat according to I except that the end-point voltage is 60-65 volts in C-3.

2. Prime according to II-A.

- 3. Bond according to IIB except that a 3/8" overlap is formed in B-5.
- 1s formed in B-5.
 4. Test per para. 4.3.4.4 MIL-A-8431.
- F. Determination of the effect of elevated temperature aging prior to priming and bonding on the lap shear strength of "light" Dow #17 treated (60-65 volts end-point) magnesium-thorium specimens.
 - 1. Dow #17 treat according to I except that the end-point voltage is 60-65 volts in C-3.

2. Age at 5000F for 10 hours.

3. Prime and bond according to II.

- 4. Test according to III at -67°F, R.T. and 260°F.
- VI. Special Testing on "Heavy" Dow #17 Treated (90-95 Volt End-Point) Magnesium-Thorium Panels
 - A. Determination of the effect of elevated temperature aging prior to priming and bonding on the lap shear strength of "heavy" Dow #17 treated (90-95 volt end-point) magnesium-thorium specimens.
 - 1. Dow #17 treat according to I except that the end-point voltage is 90-95 volts in C-3.

2. Age at 500°F for 10 hours.

3. Prime and bond according to II.

- 4. Test according to III at room temperature.
- VII. X-Ray Diffraction Studies on Dow #17 Coatings
 - A. Apply Dow #17 treatment according to I, using end-point voltage of 60-65 volts, 70-75 volts and 90-95 volts in C-3.
 - B. Scrape coating from treated panels.
 - C. Place scrapings in X-ray diffraction powder camera (Norelco X-Ray Diffraction Powder Camera Model No. 12045).
 - D. Make diffraction pattern using a three-hour exposure to copper radiation.
 - E. Interpret pattern by comparison with A.S.T.M. Standard Patterns of Chemical Compounds.

RESULTS

A summary of the test results is given in Table I and is illustrated in Figures 1 through 3. The results are given in detail in Tables II through XVI. (See Table Index on Page 1).

DISCUSSION

The Dow #17 treatment applied to magnesium-thorium gives protection against corrosion and at the same time offers a potentially pod surface for adhesive bonding. Before the Dow #17 treated an agnesium-thorium could be utilized to maximum benefit in production it was necessary to make a study of its basic properties as a bonding-surface preparation. This study was designed to provide information as to the relationship between the method of application of the Dow #17 coating, its effectiveness as a bonding surface and processing variables which may be encountered during production bonding of Dow #17 coated HK-31 alloy.

Dow #17 treating HK-31 magnesium-thorium alloy results in the formation of a surface coating on the alloy which acts as an electrical insulator. In order to sustain the coating formation, a current density of approximately ten amperes per square foot of surface area must be maintained. As the thickness of the coating increases the electrical resistance also increases and, therefore, progressively higher voltage must be applied to maintain the required current density. The voltage at which the treatment is stopped is known as the "end-point" voltage.

A study of the nature of the Dow #17 coating was made which provided information as to the relationship between the chemical and physical properties of the coating and its effectiveness as a bonding surface for magnesium-thorium. Specimens given the "standard" Dow #17 treatment (70-75 volts end-point) were tested in lap shear strength at various temperatures after being primed with EC-1459 and bonded with AF-31. Additional specimens given the "standard" treatment were subjected to certain conditions before bonding and testing such as room temperature aging both before and after application of EC-1459 primer and elevated temperature aging prior to application of primer. Thus the effect of these factors on the lap shear strength was determined. Also the treated specimens were cleaned with certain solvents prior to priming, bonding and testing in order to determine the effect of such cleaning on the lap shear strength.

Among the variations in processing investigated in this test was the end-point voltage during the application of the Dow #17 treatment. The end-point voltage which showed the most promise was 60-65 volts. Specimens given this treatment primed with EC-1459 and bonded with AF-31 were tested in lap shear strength at various temperatures. When the test originator was informed of the highly satisfactory results obtained using this end-point

A DIVISION OF GENERAL DYNAMICS CORPORATION (FORT WORTH)

PAGE	10	
REPORT NO.	FGT-2000	
MODEL	B-58	
DATE 3	September	1958

voltage, it was requested that the remainder of the test be used for further study of this process ("light" Dow #17 Coating). Therefore, additional specimens treated in this manner were given more extensive testing such as normal temperature fatigue and fluid exposure. Thus a rather comprehensive evaluation was made of this "light" Dow #17 treatment as a bonding surface preparation for HK-31 magnesium-thorium alloy.

As part of the study of the Dow #17 treatment an analysis by x-ray diffraction was made of "light" "standard", and "heavy" Dow #17 coatings.

It was found in the course of this test that lap shear failure in bonded "standard" and "heavy" Dow #17 treated HK-31 is caused by failure in the coating itself, failure in the adhesive, or failure between the adhesive and the coating, while lap shear failure in bonded "light" Dow #17 treated specimens was due to failure either in the adhesive or between the adhesive and the coating. There was no failure in the coating itself.

The "light" Dow #17 treatment produced bond strengths superior to those produced by either the "standard" or "heavy" treatment, although aging at room temperature produced a slight improvement of lap shear strengths of specimens given the "standard" treatment and aging at elevated temperatures results in a significant improvement in lap shear strength.

Also, the bond strengths produced by the "light" treatment are resistant to weakening by exposure to fluids per Para. 4.2.4 MIL-A-8431. Significantly, thirty-day exposure to salt spray caused only slight corrosion on the surface of the "light" Dow #17 treated magnesium-thorium alloy. Fluid exposure tests were not performed on bonded magnesium-thorium specimens given the "standard" nor the "heavy" Dow #17 treatment.

Results of the x-ray diffraction determination showed the composition of the "heavy" Dow #17 coatings to be entirely chromium sesquioxide (Cr_2O_3) while the "light" and "standard" coats are composed of mixtures of hydrated and anhydrous lower oxides of chromium with no chromium sesquioxide present. Thus the lower oxides of chromium found in the "light" Dow #17 coating produce a good bonding surface for magnesium-thorium alloy while the chromium sesquioxide (Cr_2O_3) found in the "heavy" coating produces a poor bonding surface. It has also been shown that it is possible to change the composition of the Dow #17 coating by varying the end-point voltage during its application.

DATE 3 September 1958

CONCLUSION

- 1. The "light" (60-65 volts end-point) Dow #17 anodize process produces a satisfactory surface for adhesive bonding with AF-31 adhesive when the treated surface is coated with EC-1459 primer prior to bonding.
- 2. The "standard" (70-75 volts end-point) and heavy (80-85 volts end-point) Dow #17 anodize process do not produce a satisfactory surface for adhesive bonding with AF-31 adhesive whether the treated surface is or is not coated with EC-1459 primer.
